

## Multi Dimensional Array

**Multi Dimensional Array(2-D Array):** A multi-dimensional array is an array of arrays. 2-dimensional arrays are the most commonly used. They are used to store data in a tabular manner.

**Syntax of Declaration of Single Dimensional Array:**

Type arrayname[row\_size][column-size];

**Example:**

```
int A[10][5];
```

```
char B[5][5];
```

```
float C[6][6];
```

		Columns →				
		0	1	2	3	4
↓ Rows	0	5	12	17	9	3
	1	13	4	8	14	1
	2	9	6	3	7	21

2D Array of size 3 x 5

**2-D Array Initialization:**

```
int A[3][5] = {{5,12,17,9,3},{13,4,8,14,1},{9,6,3,7,21}};
```

**Representation of multi Dimensional Array:**

	0	1	2	....	n-1
0	a[0][0]	a[0][1]	a[0][2]	.....	a[0][n-1]
1	a[1][0]	a[1][1]	a[1][2]	.....	a[1][n-1]
2	a[2][0]	a[2][1]	a[2][2]	.....	a[2][n-1]
3	a[3][0]	a[3][1]	a[3][2]	.....	a[3][n-1]
4	a[4][0]	a[4][1]	a[4][2]	.....	a[4][n-1]
.	.	.	.	.....	.
.	.	.	.	.....	.
.	.	.	.	.....	.
n-1	a[n-1][0]	a[n-1][1]	a[n-1][2]	.....	a[n-1][n-1]

**a[n][n]**

### Address Calculation in a multi Dimensional Array:

Address of an element of a multi dimensional array is calculated in two forms given below:

#### 1. Row Major Order

The address of an element in multi dimensional array using row major order is calculated using the following formula:

$$\text{Address of } A[I][J] = B + W * [N * (I - L_R) + (J - L_C)]$$

Where,

B= (Base Address): The address of first element in an array.

W= (width): storage size (in bytes) acquired by one element in array.

I= Row subscript of element whose address is to be found.

J = Column subscript of element whose address is to be found.

$L_R$  = Lower limit of row, if not given assumed zero(0).

$L_C$  = Lower limit of column, if not given assumed zero(0).

$M$ = Number of rows of matrix.

$N$ = Number of columns of matrix.

## 2. Column Major Order

The address of an element in multi dimensional array using column major order is calculated using the following formula:

$$\text{Address of } A [ I ] [ J ] = B + W * [ ( I - L_R ) + M * ( J - L_C ) ]$$

Note: **if number of rows and columns of matrix is given as  $A [L_R \dots U_R][L_C \dots U_C]$  then,**

$$\text{Number of rows } M = (U_R - L_R) + 1$$

$$\text{Number of columns } N = (U_C - L_C) + 1$$

**Examples:**

**Q1. An array  $X [-15 \dots 10, 15 \dots 40]$  requires one byte of storage. If beginning location is 1500 determine the location of  $X [15][20]$ .**

**Solution:**

As number of rows and columns is not given, so first calculate number of rows and columns using formula,

$$\text{Number of rows } M = (U_R - L_R) + 1$$

$$= (10 - (-15)) + 1$$

$$= 26$$

$$\text{Number of columns } N = (U_C - L_C) + 1$$

$$= (40 - 15) + 1$$

$$= 26$$

### a. Row major wise

**Address of A [ I ][ J] = B + W \* [ N \*( I - L<sub>R</sub> ) + ( J - L<sub>C</sub> ) ]**

**Where,**

**B= 1500**

**W= 1 byte**

**I= 15**

**J=20**

**N=26**

**L<sub>R</sub>= -15**

**L<sub>C</sub>= 15**

$$\text{Address of A [ 15 ][ 20]} = 1500 + 1 * [26 * (15 - (-15)) + (20 - 15)]$$

$$= 1500 + 1 * [26 * 30 + 5]$$

$$= 2285$$

**b. Column major wise**

**Address of A [ I ][ J] = B + W \* [ ( I - L<sub>R</sub> ) + M \* ( J - L<sub>C</sub> ) ]**

$$\text{Address of A [ 15 ][ 20]} = 1500 + 1 * [(15 - (-15)) + 26 * (20 - 15)]$$

$$= 1500 + 1 * [30 + 26 * 5]$$

$$= 1660$$
